## Abstract

Liver insufficiency and damage are major causes of death and disease worldwide and may result from exposure to environmental toxicants, specific combinations or dosages of pharmaceuticals, and microbial metabolites. The generation of reactive intermediates, in particular 4-hydroxynonenal (4-HNE), is a common event in liver damage caused by a variety of hepatotoxic drugs and solvents. The peroxisome proliferator-activated receptors (PPARs) are nuclear receptors that are involved in the transcriptional regulation of lipid metabolism as well as other biological functions. Importantly, we have observed that the PPAR $\beta/\delta$ <sup>-/-</sup> mouse is more susceptible to chemically induced hepatotoxicity than its wild-type counterpart, and our objective in this study was to elucidate the mechanism(s) by which PPAR $\beta/\delta$  confers protection to hepatocytes. We hypothesized that PPAR $\beta/\delta$  plays a protective role by responding to toxic lipids and altering gene expression accordingly. In support, oxidized-VLDL and constituents including 13-S-hydroxyoctadecadienoic acid (13-S-HODE) and 4-HNE are PPAR $\beta/\delta$  ligands. A structure–activity relationship was established where 4-HNE and 4-hydroperoxynonenal (4-HpNE) enhanced the activity of the PPAR $\beta/\delta$  subtype while 4-hydroxyhexenal (4-HHE), 4-oxo-2-Nonenal (4-ONE), and *trans*-4,5-epoxy-2(*E*)-decenal did not activate this receptor. Increasing PPAR $\beta/\delta$  activity with a synthetic agonist decreased sensitivity of hepatocytes to 4-HNE and other toxic agents, whereas inhibition of this receptor had the opposite result. Gene expression microarray analysis identified several important PPAR $\beta/\delta$ -regulated detoxification enzymes involved in 4-HNE metabolism that are regulated at the transcript level. This research established 4-HNE as an endogenous modulator of PPAR $\beta/\delta$  activity and raises the possibility that agonists of this nuclear receptor may be utilized to prevent or treat liver disease associated with oxidative damage.

## Introduction

Greater than 2.2 million hospitalized Americans suffer adverse drug reactions each year, with liver toxicity presenting

as the most common adverse effect, and approximately 100,000 individuals die unintentionally from administration of medications [1,2]. Many additional cases of liver failure occur due to acute, chronic, and degenerative disease processes, including those related to acetaminophen overdose, alcohol consumption, and solvent exposures. Reactive oxygen intermediates (ROI) elicit oxidative decomposition of polyunsaturated fatty acids (i.e., lipid peroxidation), leading to the formation of a complex mixture of aldehydic end products, including malondialdehyde (MDA), 4-HNE, and other alkenals [3]. These aldehydic molecules have been considered the ultimate mediators of toxic effects elicited by oxidative stress but may also affect cellular function at nontoxic levels via signal transduction, gene expression, and cell proliferation. Although the overt toxicity

<sup>1</sup> These authors contributed equally to this work.

caused by aldehydic end products is due primarily to covalent binding to cellular macromolecules, the effects on signal transduction are not well characterized. Since millions of individuals suffer adverse drug reactions each year it is important to understand how the cell responds to intracellular insults such as production of ROI and 4-HNE.

The peroxisome proliferator-activated receptors (PPARs) are nuclear receptors that exist as three subtypes ( $\alpha$ ,  $\beta/\delta$ , and  $\gamma$ ), which exhibit tissue-specific expression, preferential ligand recognition, and distinct biological functions [4–9]. Although important as targets of pharmaceutical intervention, there is increasing evidence that the biological niche occupied by the PPARs is that of a receptor for fatty acid and their metabolites. Of the three PPAR genes ( $\alpha$ ,  $\beta/\delta$ , and  $\gamma$ ), the PPAR $\beta/\delta$  isoform is the least well studied in terms of its biological functions and endogenous ligands. PPAR $\beta/\delta$  plays an important role in differentiation of epithelial tissues, fatty acid catabolism in skeletal muscle, improvement of insulin sensitivity, attenuated weight gain, and elevated HDL levels [10]. Emerging evidence suggests that the presence of this receptor is important in ameliorating the effects of hepatotoxicants. For example, histological examination of liver and analysis of markers of overt damage to this organ (serum GPT) after treatment with the xenobiotics azoxymethane (AOM), arsenic, or carbon tetrachloride demonstrated that the extent of liver toxicity in PPAR $\beta/\delta$ -null mice was more severe than in wild-type mice.<sup>2</sup> While it is remotely possible that the metabolic fate of these hepatotoxicants could be influenced by PPAR $\beta/\delta$ , it is more likely that regulation of oxidative stress underlies the protective role of this receptor in liver. These chemicals share a common mechanism of overt toxicity via production of ROI and oxidized lipid intermediates. For example, CCl<sub>4</sub> affects eicosanoid pathways [11,12] and increases circulating prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) levels [13] and 4-HNE and 4-HNE-protein adducts [3,14,15]. The purpose of this study was to determine the extent to which oxidized lipids and their metabolites interact with PPAR $\beta/\delta$  and influence gene regulation. We hypothesized that PPAR $\beta/\delta$  acts as an oxidative stress sensor in hepatocytes and, upon interaction with products of lipid peroxidation, regulates detoxification genes accordingly to ameliorate the toxic insult.

One possible explanation for the increased susceptibility of PPAR $\beta/\delta$ <sup>-/-</sup> mice to hepatotoxicity is that oxidative damage increases the production of an endogenous ligand for PPAR $\beta/\delta$ . This putative agonist would in turn stimulate lipid metabolism and degradation of lipid peroxidation intermediates. PPARs are well recognized as transcriptional regulators of lipid metabolism, transport, storage, and other activities [16]. In the absence of PPAR $\beta/\delta$  the signaling cascade would be disrupted and accumulation of toxic lipids such as 4-HNE would result. If our hypothesis were correct, endogenous ligands of PPAR $\beta/\delta$  should include oxidized lipids, in particular those derived from fatty acids. In support, we discovered that oxidized-VLDL and constituents including 13-S-HODE and 4-HNE are PPAR $\beta/\delta$

agonists. In addition, modulating PPAR $\beta/\delta$  activity, either by activation with synthetic PPAR $\beta/\delta$ -selective agonist tetradecylthioacetic acid (TTA) or inhibition with PPAR pan-antagonist GW9662 [17], affects the sensitivity of hepatocytes to 4-HNE and other toxic agents. This research raises the possibility that PPAR $\beta/\delta$  agonists may be utilized to prevent or treat liver disease associated with the generation of ROIs.

## Materials and methods

### Reagents

VLDL (human plasma) was purchased from Calbiochem (La Jolla, CA), LPL was purchased from Sigma (lyophilized powder) and reconstituted in PBS (10 mg/mL), and 13-S-HODE, 13-S-HpODE, 4-HHE, 4-ONE, *trans*-4,5-epoxy-2E-decenal, 4-HpNE, and 4-HNE were purchased from Cayman Chemical (Ann Arbor, MI) and used without further purification. The semiozymatic synthesis and purification of some of the linoleic and arachidonic acid oxidation products such as 9-HODE, 12-HpODE, 5-HETE, 9-HETE, 12-HETE, 15-HETE, 5-HpETE, 15-HpETE, 5,15-diHpETE, and 5,6-diHETE were performed as described [18]. The authenticity of each of the lipid mediators was confirmed using cochromatography as well as gas chromatography-mass spectrometric experiments. UV-visible spectroscopy was used to determine their respective concentrations, and the compounds were reconstituted in anhydrous ethanol to the desired concentration. The compounds were used within 30 min of reconstitution in ethanol.

### Plasmids

Plasmids used in reporter assays including pM/mPPAR- $\alpha$ , - $\beta$ , and - $\gamma$ , pBK/mPPAR- $\alpha$ , - $\beta$ , and - $\gamma$  (murine), ACO Luciferase, and pFR-luciferase (Promega) have been described elsewhere [19].

### Cell culture

3T3-L1 preadipocyte cells were grown in standard high-glucose Dulbecco's modified Eagle medium (DMEM) containing 10% fetal bovine serum (FBS) at 37°C and 5% CO<sub>2</sub>. MuSH cells were grown in standard  $\alpha$ -MEM containing 10% FBS. Cells were treated as described in the figure legends.

### Transient transfection and treatment

Cells were counted using a hemocytometer following staining with trypan blue solution (0.4%) (Sigma) and plated onto 10-cm dishes at densities between 600,000 and 800,000 cells/dish for transfection. Transfections were performed at 37°C for 6 h using 12  $\mu$ g of the appropriate Gal4-PPAR ligand binding domain (LBD) plasmid (pM/mPPAR- $\alpha$ , - $\beta$ , or - $\gamma$ ) containing a Luciferase reporter, and 24  $\mu$ g Lipofectamine (Invitrogen). Transfection media were then replaced with fresh high-glucose DMEM after washing the dishes with PBS and the cells were allowed to recover overnight.

<sup>2</sup> W. Shan et al., manuscript in preparation.

Cells were reseeded into 96-well plates (Costar, Corning, NY) 24 h following transfection and allowed to sit undisturbed at 37°C for 2–3 h to adhere to the well bottom. The media were removed and 100  $\mu$ L of fresh media containing the compound of interest at the desired concentration was added to the cells. Treatments were performed for 12 h at 37°C and 5% CO<sub>2</sub>.

#### *VLDL experiments*

VLDL control experiments used DMSO (the vehicle for positive controls ciprofibrate, tetradecylthioacetic acid, and rosiglitazone for PPAR $\alpha$ , - $\beta/\delta$ , and - $\gamma$ , respectively) only in a volume equal to the highest volume used for positive controls, as well as a CuSO<sub>4</sub> control at 10  $\mu$ M. All solutions were prepared in a sterile environment using high-glucose DMEM and were allowed to incubate at 37°C for 1 h prior to treatment. Cells received VLDL and oxVLDL at 10  $\mu$ g/mL. VLDL and oxVLDL were treated with 1  $\mu$ L each of Lipoprotein lipase (LpL, 715 units/ $\mu$ L) and allowed to incubate at 37°C without shaking for 1 h prior to treatment.

#### *13-S-HODE and 4-HNE experiments*

Fatty acid treatment experiments used ethanol (EtOH; the vehicle for 13-S-HODE and other fatty acids and their metabolites) only in a volume equal to the highest volume used for 13-S-HODE or 4-HNE. Cells received 13-S-HODE and other fatty acids at 50  $\mu$ M and 4-HNE at 25  $\mu$ M, except where indicated.

#### *Oxidation of VLDL and 13-S-HODE with Cu<sup>2+</sup>*

Copper solutions (10  $\mu$ M) were prepared fresh for every experiment from a stock solution of aqueous CuSO<sub>4</sub> at 20 mM. VLDL and 13-S-HODE solutions were treated with an equal volume of aqueous CuSO<sub>4</sub> and allowed to incubate at 37°C in an incubator/shaker for a period of 72 h, unless otherwise indicated.

#### *Temperature-sensitive SV40 virus preparation*

CV-1 cells were grown to confluence in T-75 flasks at 37°C in  $\alpha$ -MEM-4% FBS. Cells were incubated with stock temperature-sensitive SV40 virus [20] at 37°C and agitated every 15 min for 2 h. Media were changed to  $\alpha$ -MEM-8% FBS, and the cells were incubated at 34°C for 7 days. Virus-containing media were removed upon gross cell pathology (nuclear inclusion, cytoplasmic vacuolation, and lysis) and stored in liquid nitrogen. Quantification of virus titer was not performed.

#### *Isolation, maintenance, and infection of primary hepatocytes*

The isolation and infection of hepatocytes were adapted from a previously described method [21]. Purebred wild-type and PPAR $\beta$ -null mice on a SV/129 background were used and have been previously described [22,23]. Primary hepatocytes were

isolated from two male wild-type mice (10 days old) and two male PPAR $\beta$ -null mice (5 days old). Mice were euthanized by overexposure to carbon dioxide and whole liver was removed and incubated at 37°C with 1% collagenase in Hanks buffered saline solution (HBSS) for 5 min. Hepatocytes were isolated by centrifugation in 10% Percoll (Amersham, Piscataway, NJ) in HBSS at 1000 rpm for 20 min at 4°C. The cells were washed with 10% FBS in  $\alpha$ -MEM, centrifuged, and resuspended in  $\alpha$ -MEM-10% FBS. Each liver was separated into three populations to be infected separately; individual clones were not selected. Cells were cultured with  $\alpha$ -MEM, 4% FBS, dexamethasone (dex), and 1% penicillin/streptomycin and allowed to grow to approximately 75% confluency at 34°C. The cells were then washed with  $\alpha$ -MEM-10% FBS, overlaid with 1 mL of  $\alpha$ -MEM-10% FBS, and infected with 200  $\mu$ L of stock virus per well. Cells were incubated at 34°C for 2–3 h and gently agitated by hand. Virus-containing media were then aspirated, and the cells were given  $\alpha$ -MEM-4% FBS-0.1  $\mu$ M dex. Media were changed twice weekly for approximately 6 weeks. Resultant colonies were isolated as mixed populations (murine SV40-immortalized hepatocytes (MuSH)) or as individual clones and are designated MuSH WT (wild-type) or MuSH $\beta/\delta^{-/-}$  (PPAR $\beta/\delta$  null).

#### *Messenger RNA examination*

MuSH WT and MuSH  $\beta/\delta^{-/-}$  cells were grown in  $\alpha$ -MEM containing 10% FBS, 100 units/mL penicillin, and 100  $\mu$ g/mL streptomycin. MuSH cells were grown to 75% confluency and treated overnight with the compound of interest. Total RNA was isolated using Tri-Reagent. Quantitative reverse transcriptase polymerase chain reaction (RT-PCR) was performed to measure  $\beta$ -actin, and adipose differentiation related protein (ADRP) mRNA levels. The following ADRP gene-specific primers were synthesized and used: 5'-AGTGGAAAGAGAAGCATCGGCT-3' (forward) and 5'-TCGATGTGCTCAACACAGTGG-3' (reverse);  $\beta$ -actin primers have been described elsewhere [19].

#### *Mouse oligonucleotide arrays*

The Mouse Genome Oligo Set Version 1 was purchased from Operon (Alameda, CA) and contains 6800 optimized 70-mer plus 24 controls, melting temperature normalized to 78°C. Sequences were optimized by the manufacturer using BLAST against all known mouse genes to minimize cross-hybridization. Oligonucleotides were printed onto glass slides using Gene-Machines Omnigrid (San Carlos, CA) with additional controls obtained from Stratagene (SpotReport system, La Jolla, CA) at the Penn State University microarray core facility.

#### *Microarray analysis*

Total RNA was isolated by TriReagent (Sigma) and further purified with RNAEasy (Qiagen) according the manufacturer's instructions. Labeling and hybridization were performed as discussed previously [19,21] In the present experiments, cohybridization was performed with cDNA from three separate

experiments (all listed as Cy5/Cy3-labeled): MuSHWT/MuSH $\beta/\delta^{-/-}$ ; MuSH WT cells treated with TTA (50  $\mu\text{M}$ ) compared to DMSO 6 h after treatment (TTA/DMSO), and MuSH WT cells treated with 4-HNE (25  $\mu\text{M}$ ) compared to DMSO 6 h after treatment (4-HNE/DMSO). Statistical analysis was performed using a Student *t* test with a *P* value of 0.05 with the additional criteria of being either 2-fold increased or decreased by PPAR $\beta/\delta$  activation. Results are given as mean and *P* value and was performed in GeneSpring (7.3, Agilent Technologies).

### 13-S-HODE enzyme-linked immunosorbent assay

One hundred fifty microliters of VLDL was oxidized as described previously and incubated with 2  $\mu\text{L}$  LpL at 37°C for 1 h. Detection of 13-S-HODE was achieved by using a 13-S-HODE Correlate enzyme immunoassay kit (Assay Designs).

### Expression of mPPAR $\beta/\delta$ LBD and 4-HNE-Capture Western immunoblot analysis

Mouse PPAR $\beta/\delta$  ligand binding domain (LBD) was expressed as a His-tagged fusion in bacteria using standard approaches. The mPPAR $\beta/\delta$ LBD-His protein, thus purified, was determined to be of >60% purity. To test the nature of interaction of 4-HNE with PPAR $\beta/\delta$ , we incubated the PPAR $\beta/\delta$  (containing domains D,E/F) with 100  $\mu\text{M}$  4-HNE for 24 h in the dark. The mixture was resolved by PAGE, transferred to a polyvinyl pyrrolidone (PVDF) membrane, and probed with a goat polyclonal antibody raised against 4-HNE mixed protein adducts (Northwest Life Sciences,

Vancouver, WA) or PPAR $\beta/\delta$  (Santa Cruz). Appropriate secondary antibodies conjugated with HRP were used followed by autoradiography.

### Molecular modeling

Molecular modeling employed MacroModel v. 8.6 and the coordinates of PPAR $\beta/\delta$  bound to eicosapentaenoic acid (PDB ID: 3GWX). The carbonyl of the bound fatty acid was superimposed with the carbonyl of 4-(*S*)-hydroxynonenal. Ligand and protein residues within 6 Å were minimized to convergence using the OPLS 2003 force field.

### Results

We hypothesized that endogenous ligands for PPAR $\beta/\delta$  would include oxidized lipids, such as those derived from VLDL. The VLDL particle is a mixture of free and esterified cholesterol, triglycerides (formed from various fatty acids), and apolipoproteins. As seen in Fig. 1A, the oxidation of VLDL with CuSO<sub>4</sub> (oxVLDL) and subsequent incubation with LpL greatly increased PPAR $\beta/\delta$  activity in a dose-dependent manner (Fig. 1B). To determine which potential products released by oxVLDL are playing a role in the enhancement of PPAR $\beta/\delta$  activity, we conducted a screen of fatty acids and their CuSO<sub>4</sub> oxidation products. In Fig. 1C we show that, while 13-S-HODE alone activates PPAR $\beta/\delta$ , its oxidation product increases activity roughly twofold higher; 15-HETE was also a PPAR $\beta/\delta$  agonist. Both 13-S-HODE and its hydroperoxy derivative, 13-S-HpODE, were equally potent in their ability to activate PPAR $\beta/\delta$  (data not shown). Furthermore, we hypothesized that

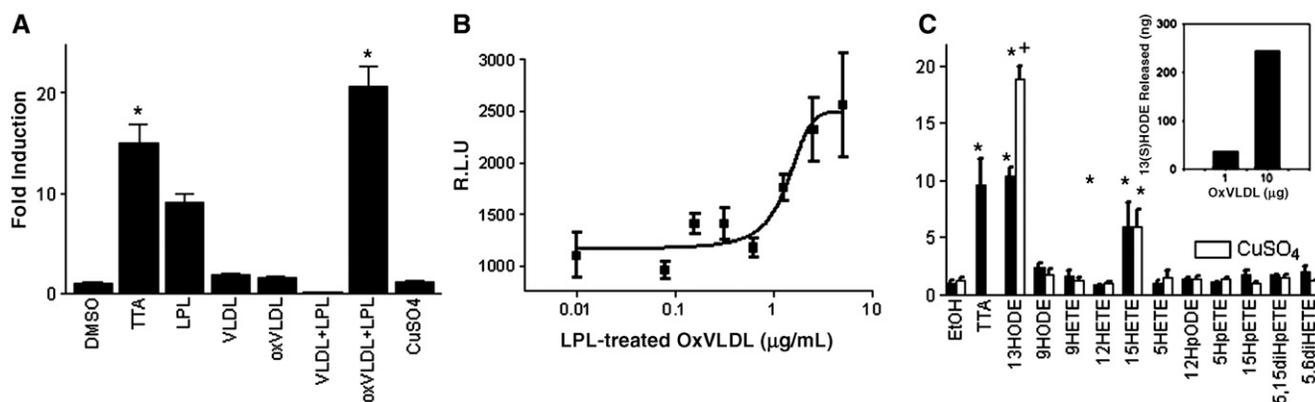

Fig. 1. (A) Oxidation of VLDL leads to increased activation of PPAR $\beta/\delta$ . VLDL (10  $\mu\text{g/mL}$ ) was oxidized with CuSO<sub>4</sub> (10  $\mu\text{M}$ ) for 72 h and then pretreated with lipoprotein lipase (LpL) for 1 h at 37°C, and the mixture was added to 3T3-L1 cells transfected with GAL4-PPAR $\beta/\delta$ -LBD and the UAS-luciferase constructs. Following treatment the cells were lysed and relative luciferase activity was determined. Results were standardized to the average DMSO-treated samples (*n* = 8, representative of two independent experiments). (B) Dose-dependent activation of PPAR $\beta/\delta$  by LpL-treated oxVLDL. 3T3-L1 preadipocytes were transfected with Gal4-LBD-mPPAR $\beta$  and treated overnight with oxidized VLDL incubated for 1 h with LpL. The cells were lysed and relative luciferase activity was determined. (*n* = 8, representative of at least three independent experiments.) (C). Oxidized 13-S-HODE is a strong PPAR $\beta/\delta$  agonist. Chemicals were obtained as described under Materials and methods. UV-visible spectroscopy was used to determine their respective concentrations, and the original solvent was evaporated under a stream of N<sub>2</sub> and the chemical reconstituted in ethanol to 50  $\mu\text{M}$ . Oxidation products were obtained via incubation with CuSO<sub>4</sub> (10  $\mu\text{M}$ ) for 72 h. 3T3-L1 preadipocytes were transfected with Gal4-LBD-mPPAR $\beta/\delta$  and UAS-luciferase constructs before being treated with compound overnight. The cells were lysed and relative luciferase activity was determined. Results were normalized to EtOH/H<sub>2</sub>O. *n* = 3. \**P* < 0.05 Significantly different than the EtOH control and + is significantly different from the unoxidized counterpart. (Inset) Oxidation of VLDL releases 13-S-HODE. VLDL was oxidized using 10  $\mu\text{M}$  CuSO<sub>4</sub> for 72 h. Oxidized VLDL was then incubated with LpL for 1 h. An ELISA specific for 13-S-HODE (Assay Designs) was performed to quantify the amount hydrolyzed from oxVLDL. Samples were prepared by diluting 1 and 10  $\mu\text{g}$  of oxVLDL with standard diluent to a final volume of 100  $\mu\text{L}$  (*n* = 2).

13-S-HODE is a component of the oxVLDL particle which is hydrolyzed upon incubation with LpL and ultimately induces PPAR $\beta/\delta$  activity. Our results show that the release of 13-S-HODE increased correspondingly with the amount of oxVLDL used (Fig. 1C, inset).

Based on the increased activity observed following CuSO<sub>4</sub> treatment of lipids, we suspected that 4-HNE or other aldehydic oxidation products formed via a Hock Cleavage mechanism from 13-S-HODE or 13-S-HpODE were PPAR $\beta/\delta$  ligands. A structure–activity relationship was established using a representative compound from each family of lipid peroxidation products, 2-alkenals, 4-hydroxy-2-alkenals, and ketoaldehydes (Fig. 2A). Reporter assays clearly showed that 4-HNE enhanced the activity of the PPAR $\beta/\delta$  subtype while 4-HHE, 4-ONE, and *trans*-4,5-epoxy-2(*E*)-decenal did not activate this receptor (Fig. 2B). Periods of oxidative stress initiate free radical-mediated oxidative damage of lipids, such as 13-S-HODE. 4-ONE results in lipid peroxidation and damage, but did not activate this receptor, showing that an indirect oxidative stress response is not responsible for activating PPAR $\beta/\delta$ . The breakdown pathway from lipid to 4-HNE includes a hydroperoxy derivative, 4-hydroperoxynonenal (4-HpNE), which is rapidly reduced to 4-HNE by cellular peroxidases. In fact, 4-HNE activated PPAR $\beta/\delta$  to a greater extent than its precursor (Fig. 2C) and did so in a dose-dependent manner (Fig. 2D, EC<sub>50</sub>16  $\mu$ M), while cellular toxicity was observed at concentrations higher than 30  $\mu$ M.

In order to analyze if 4-HNE affected gene expression or toxicity in a PPAR $\beta/\delta$ -dependent manner, studies were performed using murine SV40-immortalized hepatocytes prepared from wild-type (MuSH WT) and PPAR $\beta/\delta$ <sup>-/-</sup> (MuSH $\beta/\delta$ <sup>-/-</sup>) mice [21]. The expression of a PPAR $\beta/\delta$ -regulated gene, adipose differentiation-related protein (ADRP [16]), was up-regulated in a PPAR $\beta/\delta$ -dependent manner in cells treated with 13-S-HODE and 4-HNE (Fig. 3A). Importantly, the cells lacking PPAR $\beta/\delta$  were more susceptible to 4-HNE cytotoxicity than the wild-type cells (Fig. 3B). The EC<sub>50</sub> value for MuSH WT cells (68  $\mu$ M) was approximately 10-times higher than that observed for the MuSH $\beta/\delta$ <sup>-/-</sup> cells (5  $\mu$ M). Also, the MuSH $\beta/\delta$ <sup>-/-</sup> cells showed overt toxicity at lower concentrations of sodium arsenite than their wild-type counterpart (Fig. 3C), thus confirming the increased hepatotoxicity observed *in vivo* in the PPAR $\beta/\delta$ <sup>-/-</sup> mouse model (data not shown). To further examine the role of PPAR $\beta/\delta$  activity on conferring resistance to 4-HNE cytotoxicity, immortalized hepatocytes (MuSH WT) were pretreated with either a PPAR $\beta/\delta$  agonist tetradecylthioacetic acid or PPAR antagonist GW9662 (at concentrations known to inhibit PPAR $\beta/\delta$  [17]) prior to 4-HNE administration. Pretreating hepatocytes with TTA resulted in a significant protection from 4-HNE-dependent toxicity (Fig. 3D). Conversely, treating MuSH WT cells with GW9662 increased sensitivity to this toxic lipid (Fig. 3E). These data clearly show a role for PPAR $\beta/\delta$  in cyto-protection against at least one aldehydic toxic lipid (4-HNE)

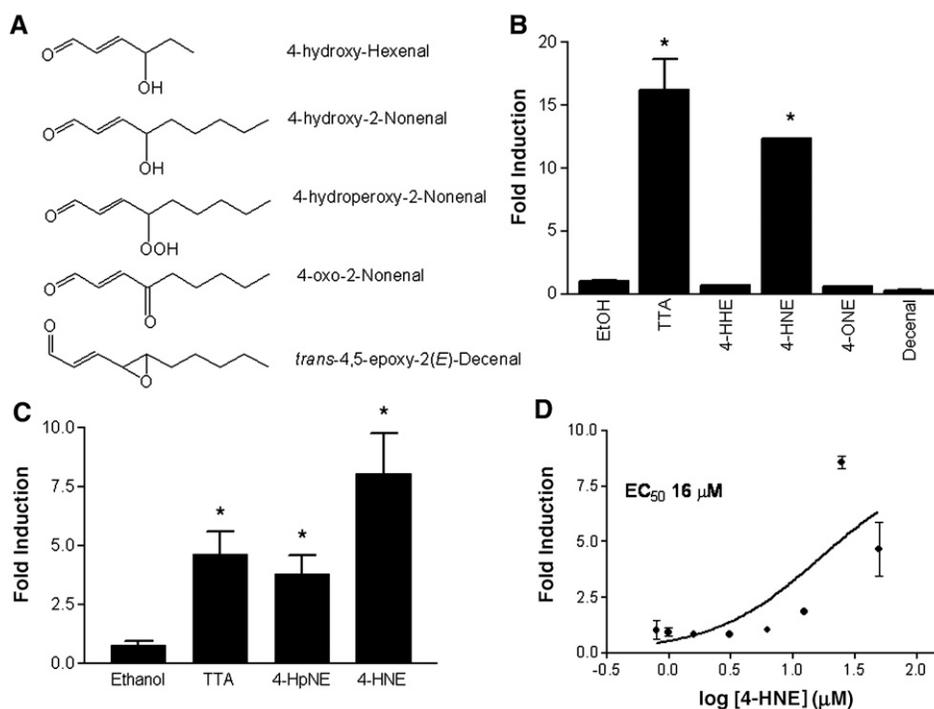

Fig. 2. (A) Structures of 4-HNE and other test molecules examined. (B) PPAR $\beta/\delta$  is activated by 4-HNE. 3T3-L1 preadipocytes were transfected with Gal4-LBD-mPPAR $\beta/\delta$  and UAS-luciferase constructs followed by treatment with each of the lipid peroxidation products or vehicle control for 12 h. Following the treatment, cells were lysed and luciferase activity was determined and normalized to EtOH. Treatment was with 25  $\mu$ M 4-HHE, 4-HNE, 4-ONE, and *trans*-4,5-epoxy-2E-decenal (Decenal; Cayman) overnight. \**P*<0.05 compared to vehicle control. (C) HpNE activates PPAR $\beta/\delta$ . Cells were treated with 25  $\mu$ M 4-HpNE or 4-HNE for 12 h as described above. \**P*<0.05 compared to vehicle control. (D) Dose–response of PPAR $\beta/\delta$  activation by 4-HNE. PPAR $\beta/\delta$  activity is increased with the addition of 25  $\mu$ M 4-HNE, while cellular toxicity is observed at higher concentrations. *n* = 8. \**P*<0.05 compared to vehicle control.

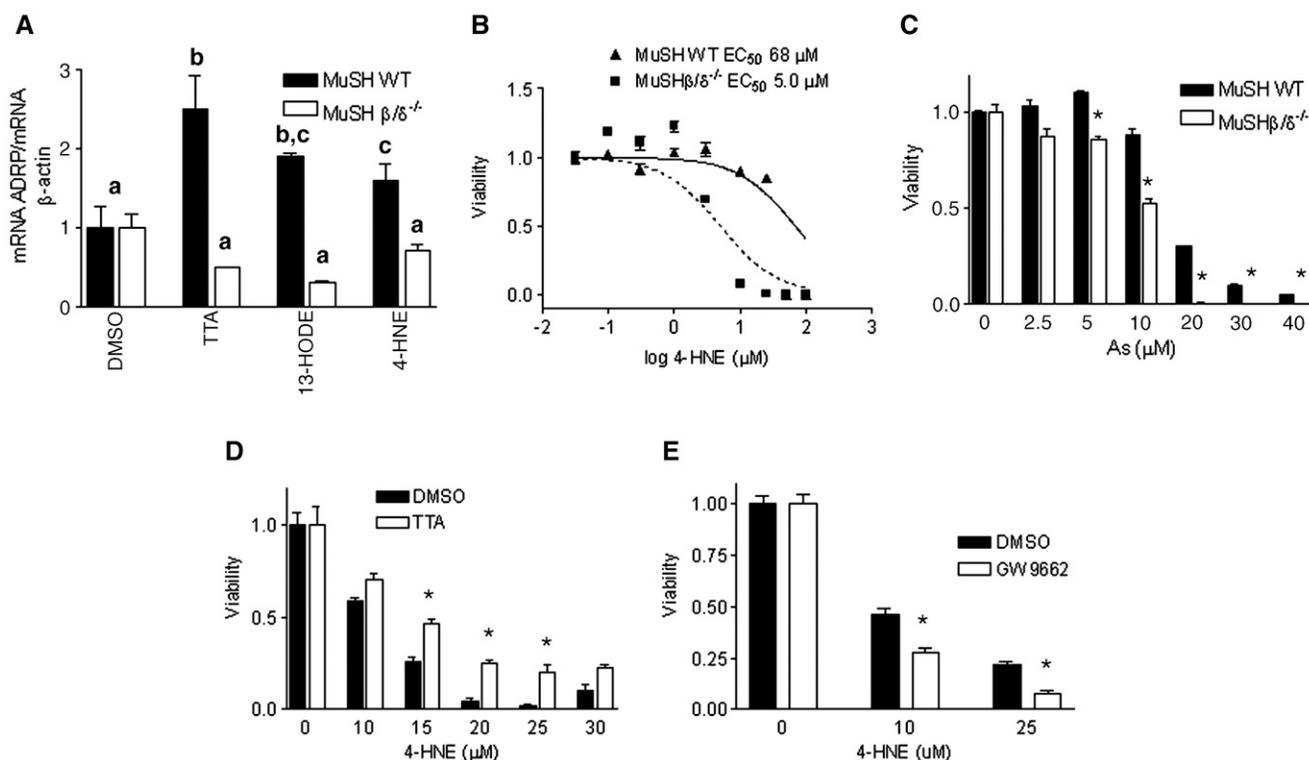

Fig. 3. (A) 4-HNE regulates gene expression in a PPAR $\beta/\delta$ -dependent manner. MuSH WT and MuSH $\beta/\delta^{-/-}$  cells were treated with 13-S-HODE and 4-HNE overnight and the cells were lysed. Total RNA was extracted using Tri-Reagent and RT-PCR performed for ADRP and corrected for  $\beta$ -actin expression.  $n = 3$ . ANOVA with Fishers multiple comparisons test was performed in Minitab (State College, PA). Bars with different letters are significantly different ( $P < 0.05$ ). (B) PPAR $\beta/\delta$  is crucial in ameliorating the toxic effects of 4-HNE. MuSHWT and MuSH $\beta/\delta^{-/-}$  hepatocytes were treated with 0, 0.1, 0.3, 1, 3, 10, or 25  $\mu\text{M}$  4-HNE for 24 h. Hepatocytes treated with concentrations of 50  $\mu\text{M}$  or higher 4-HNE do not survive, regardless of genotype. The data are normalized for percentage viable cells, shown on the y-axis.  $n = 8$ . Representative of six independent experiments. (C) PPAR $\beta/\delta^{-/-}$  cells are more sensitive to arsenic-induced toxicity. MuSHWT and MuSH $\beta/\delta^{-/-}$  hepatocytes were treated to graded concentrations of sodium arsenite for 24 h. The data are normalized for percentage viable cells, shown on the y-axis.  $n = 5$ . Representative of two independent experiments. \* $P < 0.05$  compared with MuSH PPAR $\beta/\delta^{-/-}$  hepatocytes. (D). Activation of PPAR $\beta/\delta$  leads to protection from oxidative damage. MuSHWT cells were pretreated with vehicle or TTA (25  $\mu\text{M}$ ) for 6 h prior to treatment with 4-HNE.  $n = 5$ . \* $P < 0.05$  compared to vehicle-treated counterpart. (E). Inhibition of PPAR $\beta/\delta$  leads to increased susceptibility to oxidative damage. MuSHWT cells were pretreated with vehicle or GW9662 (10  $\mu\text{M}$ ) for 6 h prior to treatment with 4-HNE.  $n = 5$ . \* $P < 0.05$  compared to vehicle-treated counterpart.

and a xenobiotic which mediates its toxicity at least in part via oxidative mediators (As). Also, this raises the possibility that one can augment PPAR $\beta/\delta$  activity in order to protect cells from the damaging affects of 4-HNE.

Gene expression affected by PPAR $\beta/\delta$  activation was examined by gene expression microarray. Of the 6800 unique genes on the arrays, 1001 gave a reliable signal in all three slides. The determination of statistically significant regulated genes was examined as we have previously reported [19,21]. Using this conservative measure of significance ( $P < 0.05$  and a twofold change in gene expression), 41 genes were regulated in a PPAR $\beta/\delta$  manner in MuSH WT cells, and in this case all were increased in levels relative to controls (Table 1). The biotransformation of 4-HNE to less toxic intermediates can be accomplished by oxidative (aldehyde dehydrogenase; ALDH), reductive (alcohol dehydrogenase; ADH), and conjugative (glutathione *S*-transferase; GST) pathways [24]. Following gene expression microarray experiments (see Table 1), we found activation of PPAR $\beta/\delta$  increased mRNA for Aldh3a1 (22-fold increase), Gstm3 (2.3-fold increase), and Gsto1 (2.0-fold increase). This suggests that PPAR $\beta/\delta$  acti-

vation is capable of increasing the detoxification of 4-HNE, although this will require formal confirmation.

An interaction with a nuclear receptor and 4-HNE has not been described previously and was examined in more detail using molecular modeling and the coordinates of PPAR $\beta/\delta$  bound to eicosapentaenoic acid (Fig. 4A [25]). PPAR $\beta/\delta$  bound to (*S*)-4-HNE (CPK model) in a conformation similar to the natural ligand (Fig. 4B). However, a putative hydrogen-bonding interaction between His413 (stick model) and the 4-hydroxyl group of the 4-HNE ligand (CPK model) occurs (Fig. 4C). As described above, PPAR $\beta/\delta$  was activated by 4-HpNE and 4-HNE but not 4-ONE, 4-HHE, or decanol. Thus, the association between the hydroxyl group of 4-HNE and His413 is necessary for optimal receptor activation by this class of compounds. In data not shown, the fatty acids nonenol and EPA activated PPAR $\beta/\delta$  to a similar extent as 4-HNE. This suggests that the interaction of carboxylic acids with PPAR $\beta/\delta$  proceeds by a different mechanism, one that would not require His413, but is still capable of activating the receptor. Several attempts were made at mutating His413 to either alanine or phenylalanine for a formal testing of the molecular modeling.

Table 1

However, the basal activity or that seen in the presence of PPAR $\beta/\delta$  ligands by these mutants was very low, suggesting that the His residue is critical for proper expression or folding. Although 4-HNE forms covalent adducts with cysteinyl, lysyl, and histidyl of target proteins, we were unable to show covalent interactions between 4-HNE and PPAR $\beta/\delta$  (Figs. 4D and E), strongly suggesting that the association with PPAR $\beta/\delta$  is reversible.

## Discussion

The PPARs are ligand-activated transcription factors that sense a variety of lipophilic molecules and control gene expression to maintain cellular homeostasis. Fatty acids and their metabolites are known endogenous agonists of all PPARs, with PPAR $\beta/\delta$  exhibiting similar structural and geometric

preference as PPAR $\alpha$ , whereas PPAR $\gamma$  tends to prefer long-chain polyunsaturated fatty acids [26]. PPAR $\beta/\delta$  agonists include linoleic acid, oleic acid, arachidonic acid, and EPA, which has been cocrystallized within the ligand binding domain of this nuclear receptor [25]. Prostaglandin A1 (PGA1), PGD2, and PGD1 can activate PPAR $\beta/\delta$  in reporter assays [27]. Similar to PPAR $\alpha$  and  $\gamma$ , incubation of triglyceride-rich lipoproteins with LPL results in the production of PPAR $\beta$  ligands [28,29]. We have shown here that several molecules present in oxVLDL including 15-HETE, 13-S-HODE, and 4-HNE are agonists of PPAR $\beta/\delta$  (Figs. 1 and 2). Activation of PPAR $\alpha$  and PPAR $\gamma$  by 13-S-HODE has been observed previously [30], although this molecule has been reported to be an inhibitor of PPAR $\beta/\delta$  in colon epithelial cells [31]. Our data indicating that 13-S-HODE is a PPAR $\beta/\delta$  agonist in preadipocytes may suggest cell-type-specific phenomena (Fig. 2). We have further examined the

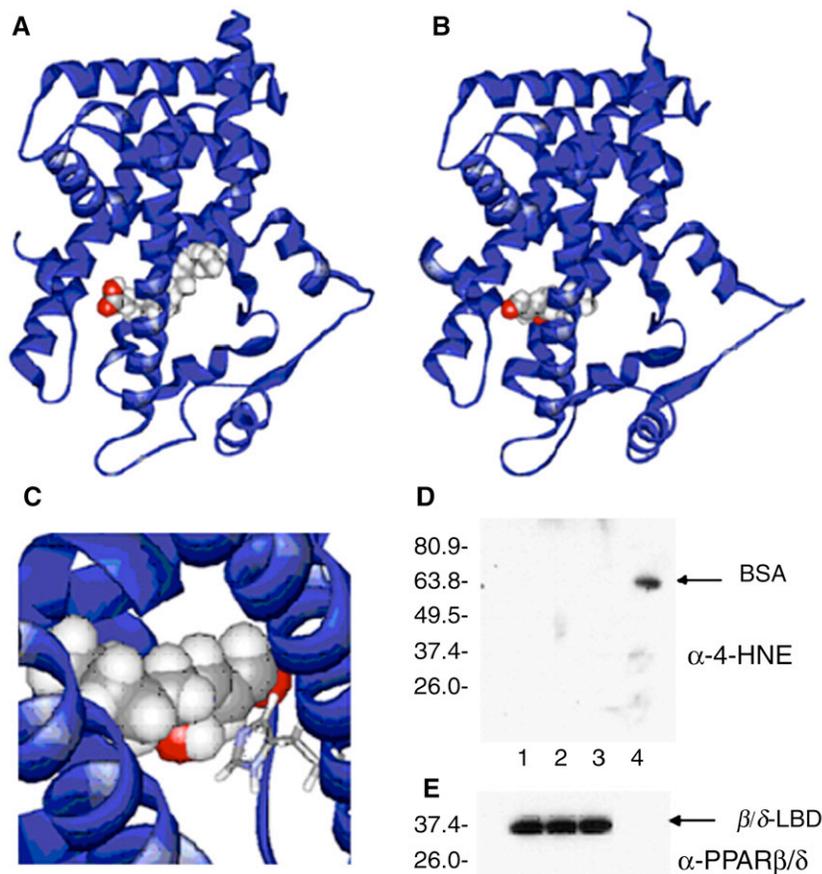

Fig. 4. (A) X-ray structure of PPAR $\beta/\delta$  bound to eicosapentaenoic acid. Model is based on coordinates from [25]. (B) A molecular model of PPAR $\beta/\delta$  bound to (*S*)-4-hydroxynonenal (CPK model) in a conformation similar to the natural ligand. (C) Visualization of the putative hydrogen-bonding interaction between His413 (stick model) and the 4-hydroxyl group of the ligand (CPK model). (D) 4-HNE activates PPAR $\beta/\delta$  via a direct and noncovalent interaction. Mouse His-tagged PPAR $\beta/\delta$  LBD was expressed in bacteria and purified using a nickel column and incubated with 4-HNE. Immunoblot analysis was used to determine 4-HNE-protein adducts. Lane 1, PPAR $\beta/\delta$ -LBD alone; Lane 2, PPAR $\beta/\delta$ -LBD plus EtOH; Lane 3, PPAR $\beta/\delta$ -LBD plus 4-HNE (100  $\mu$ M); Lane 4, BSA plus 4-HNE (100  $\mu$ M). (E) Identical incubation as performed above with immunoblot analysis of PPAR $\beta/\delta$ .

products of 13-S-HODE, via the Hock Cleavage mechanism, which forms such alkenals as HpNE and HNE, to activate PPAR $\beta/\delta$ . We clearly demonstrate that of the several lipid peroxidation products, only 4-HNE and, to a lesser extent, its hydroperoxy-derivative are capable of activating the PPAR $\beta/\delta$  receptor in transient transfection reporter assays. However, HpNE may be a relatively unstable molecule since it can be reduced to the corresponding alcohol by cellular peroxidases, including the selenium-dependent and -independent GSH peroxidases. Although it has been demonstrated that 4-HNE modulates up-regulation of PPAR $\gamma$  expression by influencing upstream kinases and troglitazone-dependent activity [32], this is the first instance of the lipid peroxidation product, 4-HNE, being described as a PPAR $\beta/\delta$  agonist. Coupled with the fact that PPAR $\beta/\delta$  is expressed virtually ubiquitously and is known to be a regulatory of several important physiological pathways makes this observation intriguing. Although the concentration of 4-HNE used in this investigation is higher than the “physiological” concentrations in several tissues and cells [33], it is very likely that high localized concentrations of 4-HNE may be formed within cells [34,35] that could be sufficient to activate this nuclear receptor.

Examination of the PPAR $\beta/\delta$  null mice has shown a role for this receptor in several biological niches [36]. There is mounting evidence that PPAR $\beta/\delta$  plays a role in ameliorating the hepatotoxic effects of a wide range of xenobiotics including arsenic and acetaminophen (APAP). Interestingly, a similar hepatoprotective role has been noted for PPAR $\alpha$  [37–39] and PPAR $\gamma$  [40] agonists, although the mechanism of this response is not clear. Studies performed with hepatocytes from wild type and PPAR $\beta/\delta^{-/-}$  mice clearly demonstrate that PPAR $\beta/\delta$  plays a pivotal role in ameliorating oxidative stress induced by the hepatotoxicant arsenic (Fig. 3C) which originates through free radical reactions and subsequent initiation of lipid peroxidation (reviewed in [11,41]). These data support our hypothesis that activation of PPAR $\beta/\delta$  by endogenous ligand such as 4-HNE may play a major role in the prevention of pathogenesis of both acute and chronic liver damage. This is further illustrated in Figs. 3D and E, where 4-HNE addition to TTA-activated MuSH wild-type cells are more resistant to oxidative stress compared to the ones that are treated with the antagonist. This is particularly relevant since the enzymatic oxygenation of arachidonic acid by the cyclooxygenase (COX), an enzyme commonly induced by hepatotoxicants,

may cause the release of reactive oxygen species (ROS) during the enzymatic reduction of hydroperoxides. The release of ROS may initiate a chain of responses that results in lipid mediators including 4-HNE with subsequent protein and DNA damage. In addition to formation of ROS and lipid peroxides, COX- and lipoxygenase (LOX)-mediated fatty acid metabolism leads to the formation of various prostaglandins and other lipid mediators depending on the various isomerases and reductases present in a tissue-specific manner. These molecules are potent bioactive compounds *in vivo* [11] and may contribute directly or indirectly to liver damage. The amount of lipid substrate, the activity of phospholipase A2 (PLA2), COX, LOX, and CYP, and various antioxidant defense mechanisms are all dynamically regulated and will ultimately affect the damage caused by a hepatotoxicant.

Thus, there are many means by which PPAR $\beta/\delta$  may be protecting the cell from oxidative damage, either by inhibiting the production of ROS and lipid intermediates or by increasing degradation of these molecules. Based on gene expression data performed herein and elsewhere [16], it appears that the most likely candidate would be PPAR $\beta/\delta$ -dependent metabolism and detoxification of lipid intermediates. The biotransformation of 4-HNE to less toxic intermediates can be accomplished by aldehyde and alcohol dehydrogenases, glutathione *S*-transferases, and perhaps other pathways [24]. Following gene expression microarray experiments, we found that activation of PPAR $\beta/\delta$  increased mRNA for *Aldh3a1*, *Gstm3*, and *Gst1*. Other microarray experiments have identified *GSTA1* and *ALDH9A1* as potential PPAR $\beta/\delta$  targets as well [16]. The induction of *Aldh3a1* and *GST1* is particularly intriguing due to their known role in protection against lipid peroxidation and toxicity [24]. Similar to the PPAR $\beta/\delta$ <sup>-/-</sup> mouse, mice that lack the transcription factor *Nrf2* are more sensitive to the cytotoxic and genotoxic effects of foreign chemicals due to attenuated induction of *Gsta1*, *Gstm1*, and *Gstm3* [42]. Thus, it is possible that these two transcription factors are sharing a common protective mechanism of action. However, in addition to being directly involved in the regulation of expression for these detoxification enzymes, PPAR $\beta/\delta$  is also sensing, or responding to, the intracellular levels of the toxic intermediate via a feedback control mechanism.

There is a wealth of information on 4-HNE as being a marker of lipid peroxidation as well as a mediator of hepatotoxicity and a variety of other pathophysiological conditions including cancer, Alzheimer's disease, and atherosclerosis [35]. Target proteins that are inhibited by 4-HNE include the glucose transporter GLUT3, tau, the proteasome, and I $\kappa$ B kinase [35] and 4-HNE causes a high frequency of G-to-T mutations in codon 249 in the p53 gene [43]. Based on the molecular modeling and Western immunoblot analyses, the covalent association of 4-HNE with cysteinyl, lysyl, and histidyl residues in PPAR $\beta/\delta$  appears to be largely reversible (Fig. 4), which is unique since 4-HNE is known to covalently modify these residues via Michael addition chemistry. In summary, we have shown that the lipid peroxidation product 4-HNE, which was regarded to be a mutagen and toxic end product for all these years, has now been demonstrated to have a nuclear receptor

modulatory activity. This receptor, PPAR $\beta/\delta$ , when activated provides a feedback regulation of gene expression that ameliorates toxicity to the liver. The discovery of 4-HNE as an endogenous ligand reveals a crosstalk of PPAR $\beta/\delta$  in cellular events involved in inflammation and energy homeostasis. Given the large number of individuals hospitalized due to chemically induced liver damage, it is attractive to speculate that this knowledge may be exploited for more effective means of protecting or treating hepatotoxicity as well as other diseases in which 4-HNE plays a causative role.
